Minimum Spanning Trees

Outline and Reading

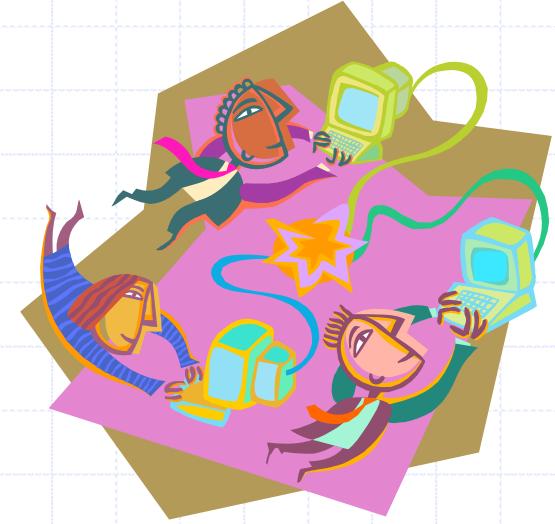

- ◆ Minimum Spanning Trees (§7.3)

- Definitions
- A crucial fact

- ◆ The Prim-Jarnik Algorithm (§7.3.2)

- ◆ Kruskal's Algorithm (§7.3.1)

- ◆ Baruvka's Algorithm (§7.3.3)

Minimum Spanning Tree

Spanning subgraph

- Subgraph of a graph G containing all the vertices of G

Spanning tree

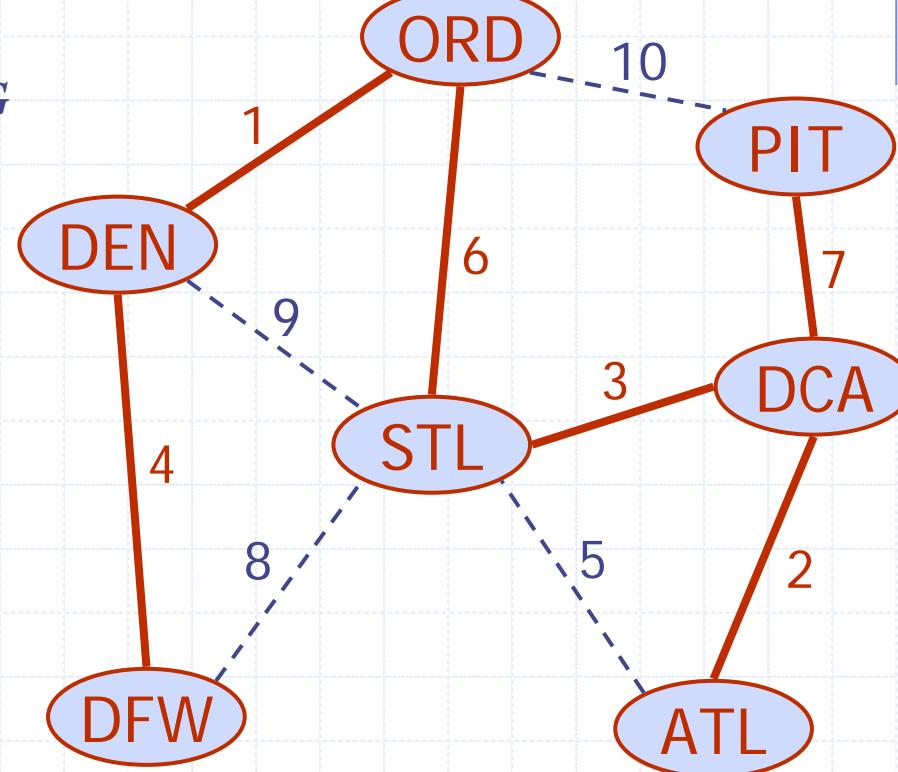

- Spanning subgraph that is itself a (free) tree

Minimum spanning tree (MST)

- Spanning tree of a weighted graph with minimum total edge weight

◆ Applications

- Communications networks
- Transportation networks

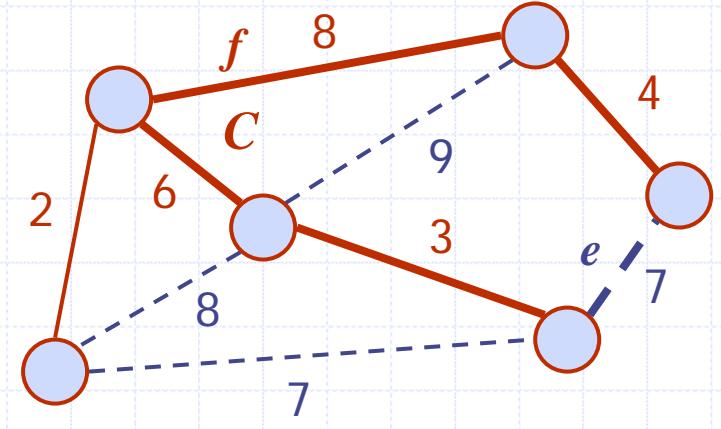

Cycle Property

Cycle Property:

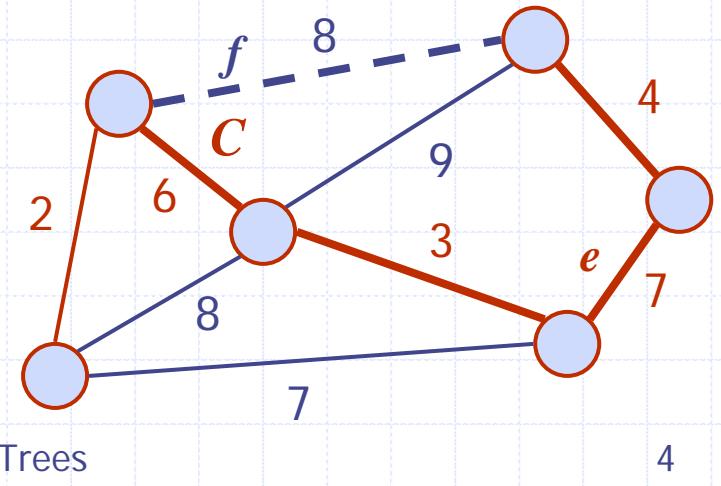

- Let T be a minimum spanning tree of a weighted graph G
- Let e be an edge of G that is not in T and C let be the cycle formed by e with T
- For every edge f of C , $\text{weight}(f) \leq \text{weight}(e)$

Proof:

- By contradiction
- If $\text{weight}(f) > \text{weight}(e)$ we can get a spanning tree of smaller weight by replacing e with f

Replacing f with e yields a better spanning tree

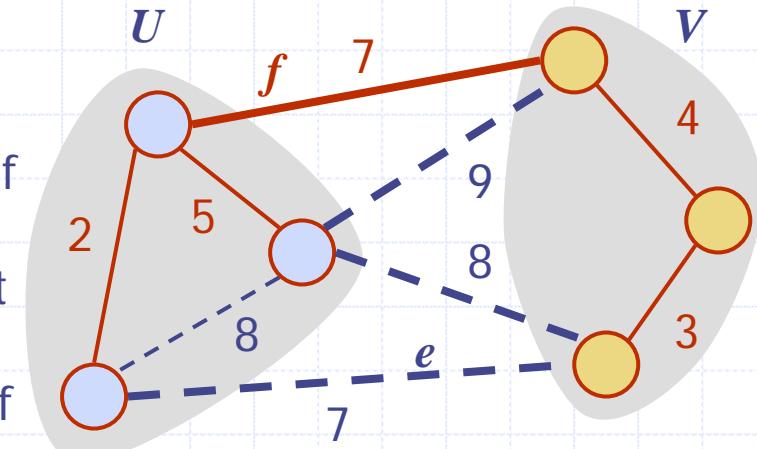

Partition Property

Partition Property:

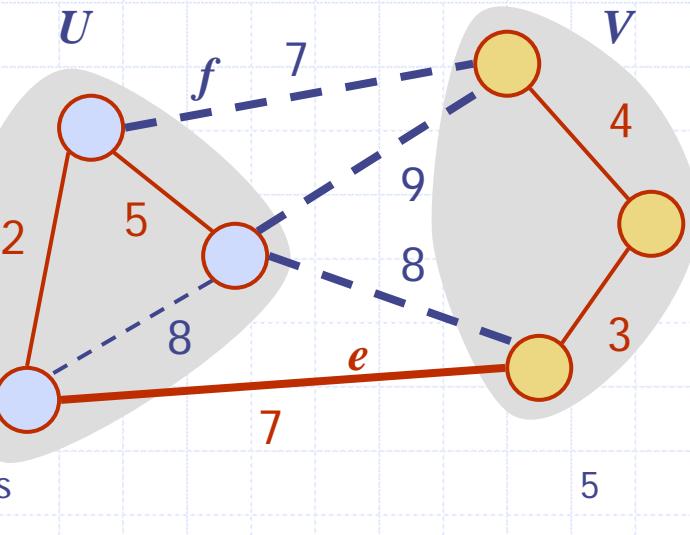

- Consider a partition of the vertices of G into subsets U and V
- Let e be an edge of minimum weight across the partition
- There is a minimum spanning tree of G containing edge e

Proof:

- Let T be an MST of G
- If T does not contain e , consider the cycle C formed by e with T and let f be an edge of C across the partition
- By the cycle property,
 $\text{weight}(f) \leq \text{weight}(e)$
- Thus, $\text{weight}(f) = \text{weight}(e)$
- We obtain another MST by replacing f with e

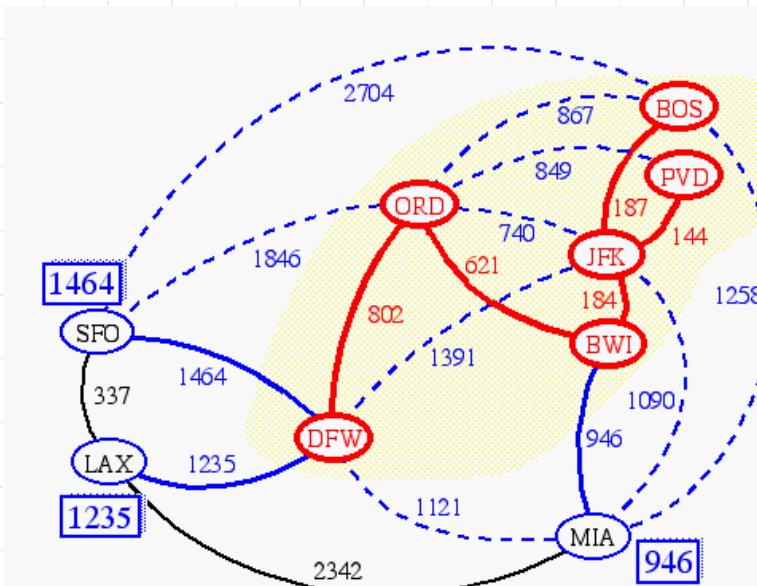

Replacing f with e yields another MST

Prim-Jarnik's Algorithm

- ◆ Similar to Dijkstra's algorithm (for a connected graph)
- ◆ We pick an arbitrary vertex s and we grow the MST as a cloud of vertices, starting from s
- ◆ We store with each vertex v a label $d(v)$ = the smallest weight of an edge connecting v to a vertex in the cloud
- ◆ At each step:
 - We add to the cloud the vertex u outside the cloud with the smallest distance label
 - We update the labels of the vertices adjacent to u

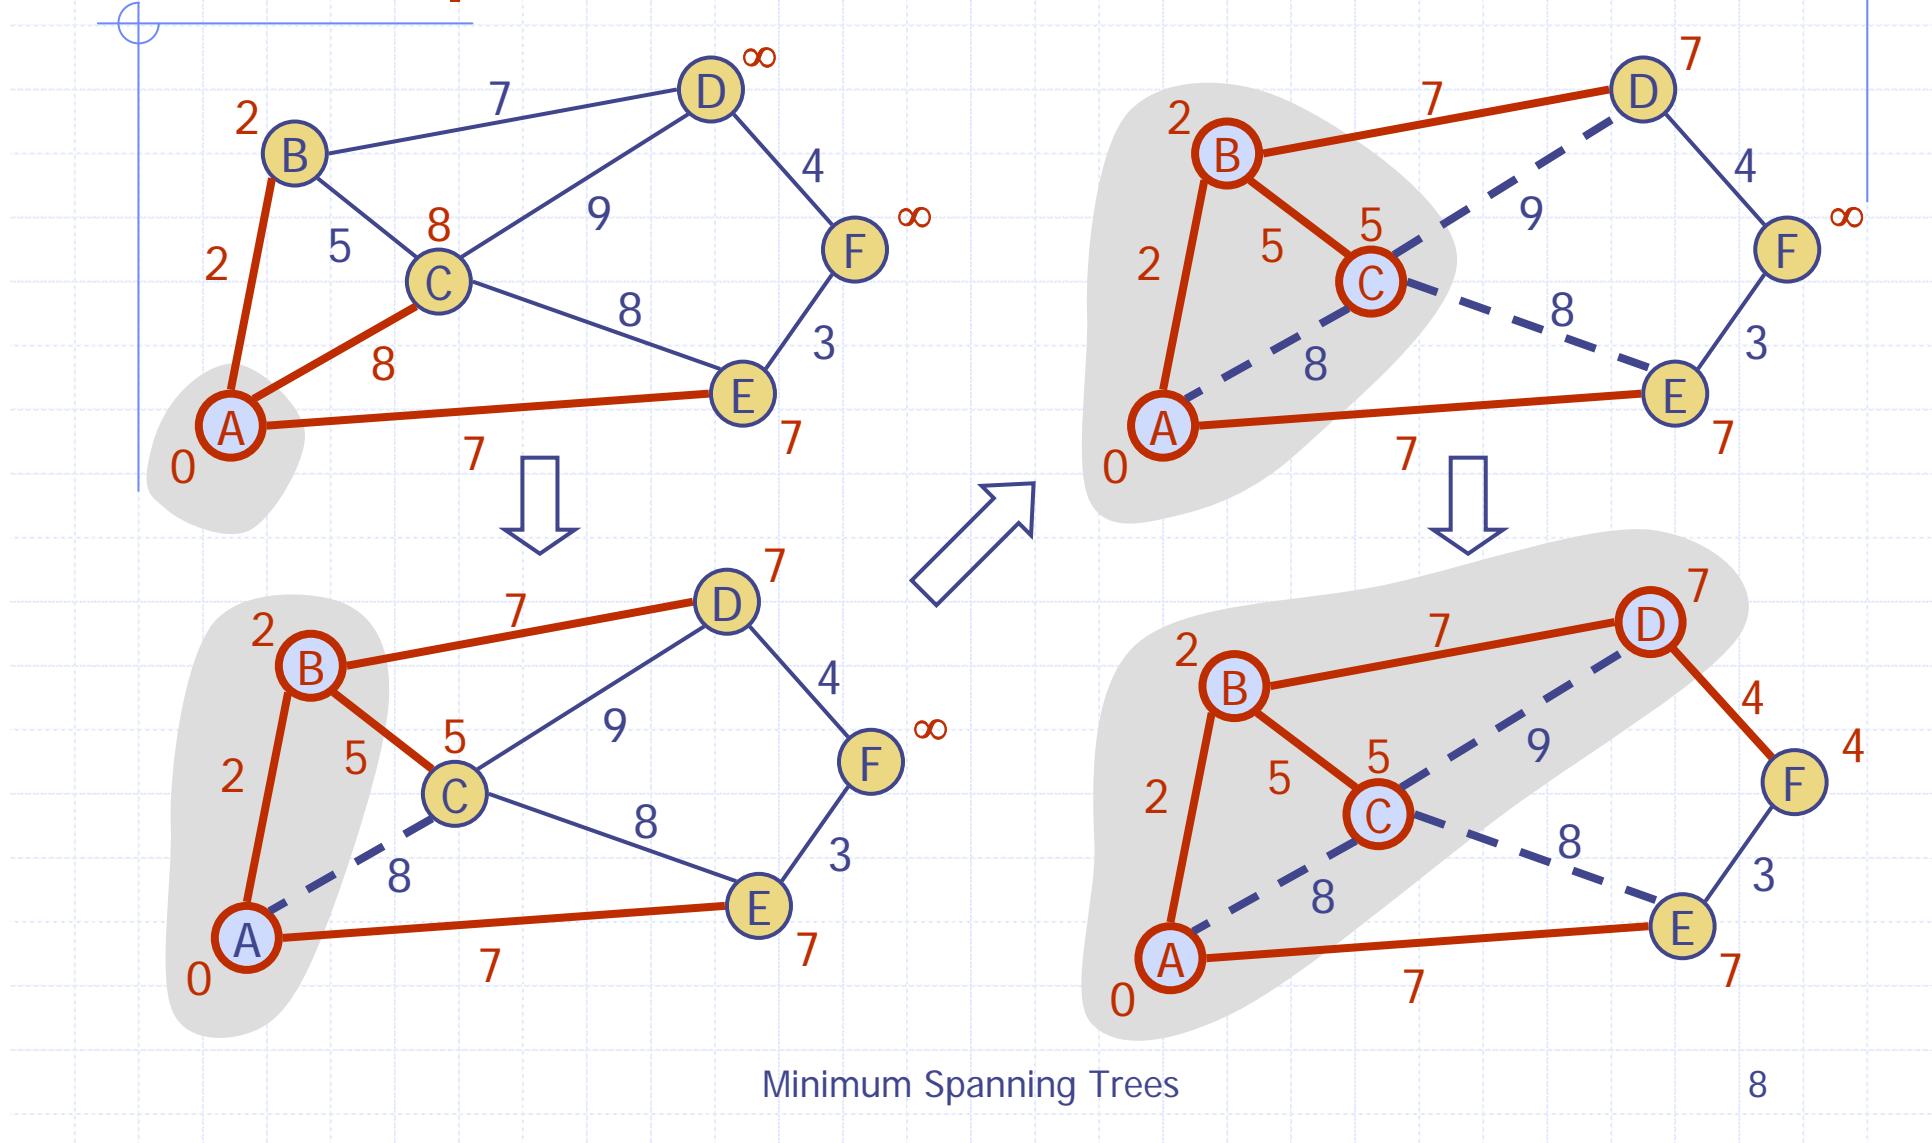

Prim-Jarnik's Algorithm (cont.)

- ◆ A priority queue stores the vertices outside the cloud
 - Key: distance
 - Element: vertex
- ◆ Locator-based methods
 - *insert(k,e)* returns a locator
 - *replaceKey(l,k)* changes the key of an item
- ◆ We store three labels with each vertex:
 - Distance
 - Parent edge in MST
 - Locator in priority queue

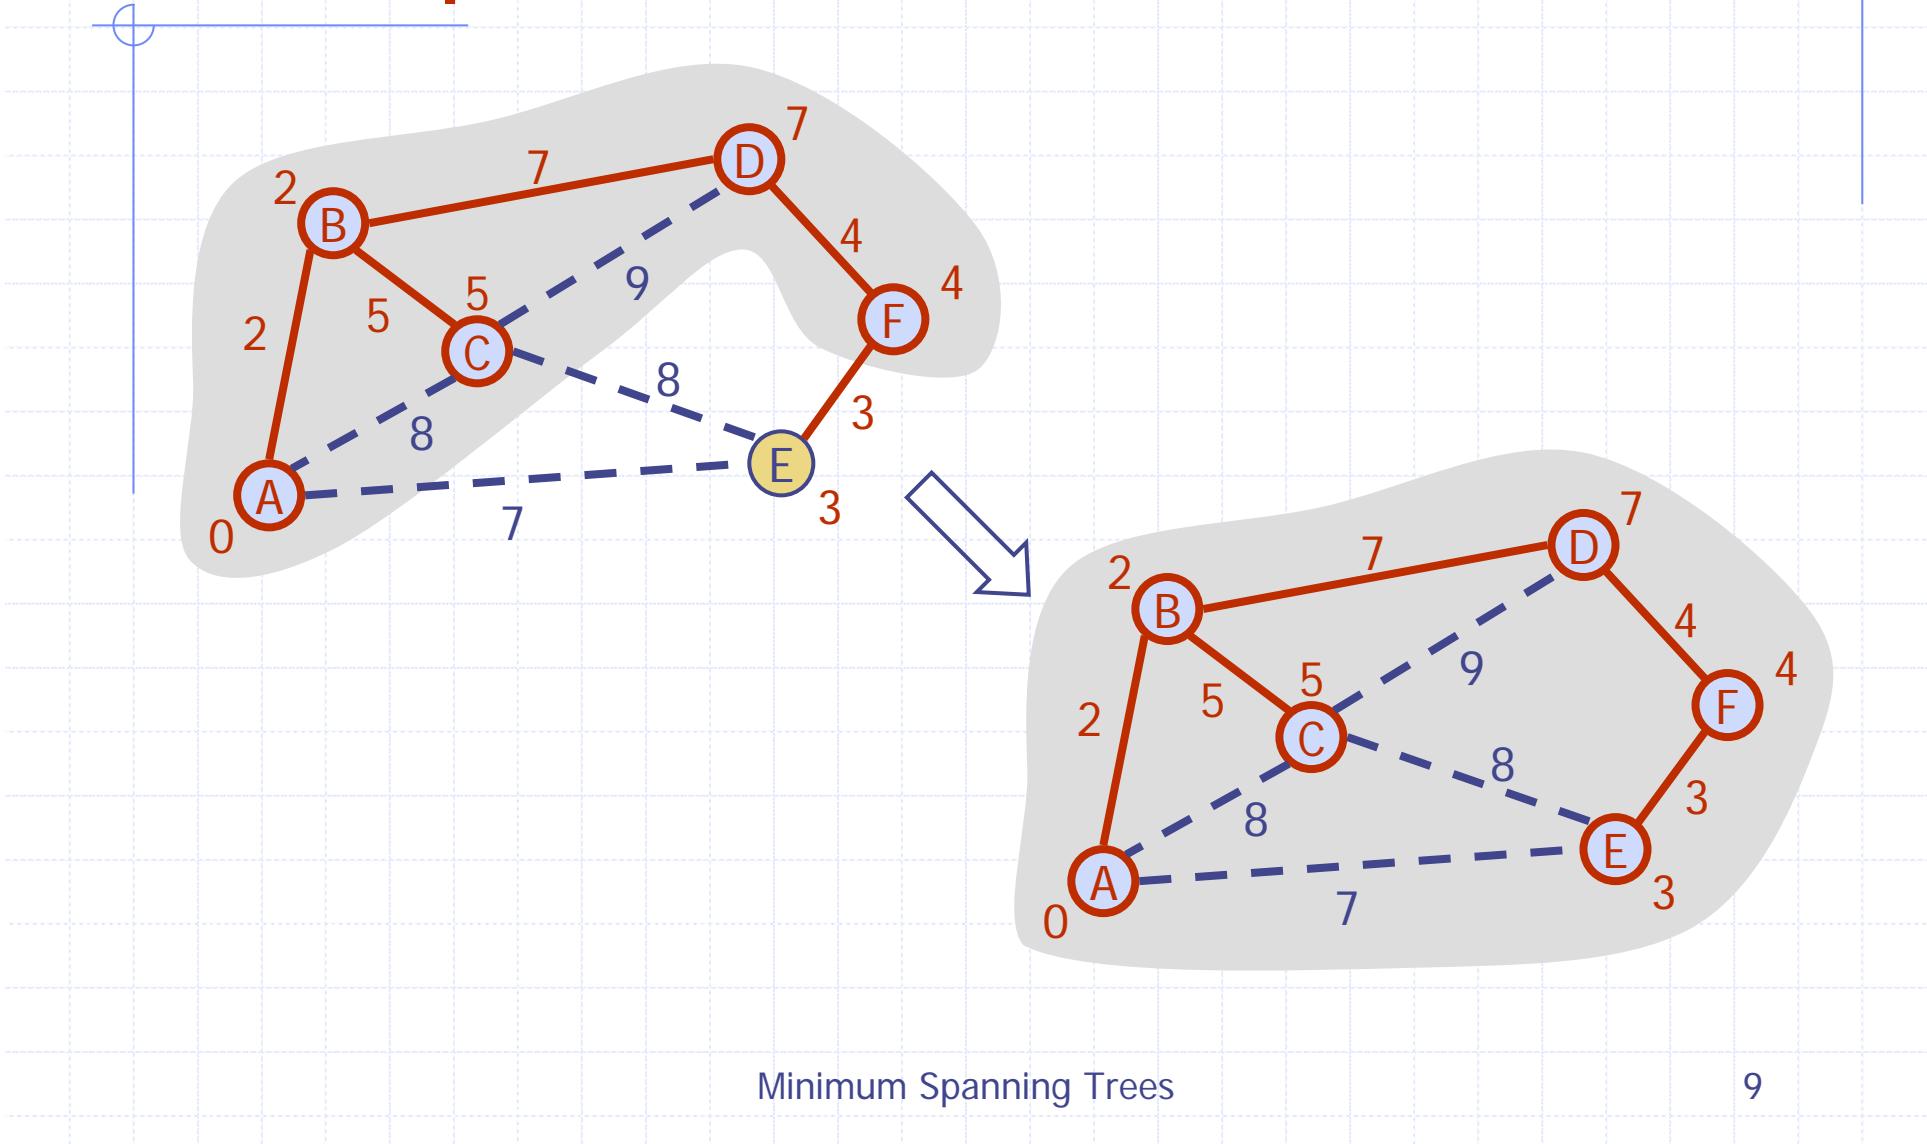

Algorithm *PrimJarnikMST(G)*

```
 $Q \leftarrow$  new heap-based priority queue  
 $s \leftarrow$  a vertex of  $G$   
for all  $v \in G.vertices()$   
    if  $v = s$   
        setDistance( $v, 0$ )  
    else  
        setDistance( $v, \infty$ )  
        setParent( $v, \emptyset$ )  
         $l \leftarrow Q.insert(getDistance(v), v)$   
        setLocator( $v, l$ )  
while  $\neg Q.isEmpty()$   
     $u \leftarrow Q.removeMin()$   
    for all  $e \in G.incidentEdges(u)$   
         $z \leftarrow G.opposite(u, e)$   
         $r \leftarrow weight(e)$   
        if  $r < getDistance(z)$   
            setDistance( $z, r$ )  
            setParent( $z, e$ )  
             $Q.replaceKey(getLocator(z), r)$ 
```

Example

Example (contd.)

Analysis

- ◆ Graph operations
 - Method `incidentEdges` is called once for each vertex
- ◆ Label operations
 - We set/get the distance, parent and locator labels of vertex z $O(\deg(z))$ times
 - Setting/getting a label takes $O(1)$ time
- ◆ Priority queue operations
 - Each vertex is inserted once into and removed once from the priority queue, where each insertion or removal takes $O(\log n)$ time
 - The key of a vertex w in the priority queue is modified at most $\deg(w)$ times, where each key change takes $O(\log n)$ time
- ◆ Prim-Jarnik's algorithm runs in $O((n + m) \log n)$ time provided the graph is represented by the adjacency list structure
 - Recall that $\sum_v \deg(v) = 2m$
- ◆ The running time is $O(m \log n)$ since the graph is connected

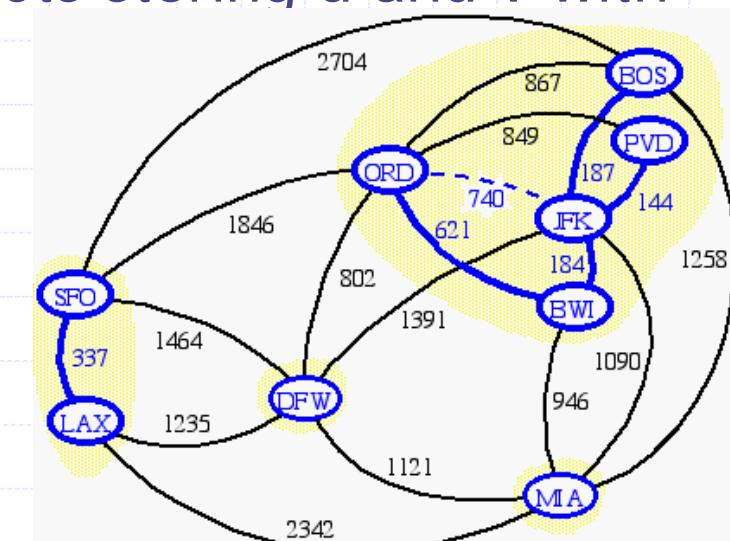

Kruskal's Algorithm

- ◆ A priority queue stores the edges outside the cloud
 - Key: weight
 - Element: edge
- ◆ At the end of the algorithm
 - We are left with one cloud that encompasses the MST
 - A tree T which is our MST

```
Algorithm KruskalMST( $G$ )
for each vertex  $V$  in  $G$  do
    define a Cloud( $v$ ) of  $\leftarrow \{v\}$ 
let  $Q$  be a priority queue.
Insert all edges into  $Q$  using their
weights as the key
 $T \leftarrow \emptyset$ 
while  $T$  has fewer than  $n-1$  edges do
    edge  $e = T.\text{removeMin}()$ 
    Let  $u, v$  be the endpoints of  $e$ 
    if Cloud( $v$ )  $\neq$  Cloud( $u$ ) then
        Add edge  $e$  to  $T$ 
        Merge Cloud( $v$ ) and Cloud( $u$ )
return  $T$ 
```

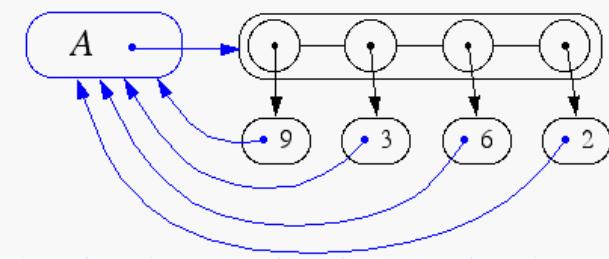

Data Structure for Kruskal Algorithm

- ◆ The algorithm maintains a forest of trees
- ◆ An edge is accepted if it connects distinct trees
- ◆ We need a data structure that maintains a **partition**, i.e., a collection of disjoint sets, with the operations:
 - find**(u): return the set storing u
 - union**(u,v): replace the sets storing u and v with their union

Minimum Spanning Trees

Representation of a Partition

- ◆ Each set is stored in a sequence
- ◆ Each element has a reference back to the set
 - operation **find**(u) takes $O(1)$ time, and returns the set of which u is a member.
 - in operation **union**(u, v), we move the elements of the smaller set to the sequence of the larger set and update their references
 - the time for operation **union**(u, v) is $\min(n_u, n_v)$, where n_u and n_v are the sizes of the sets storing u and v
- ◆ Whenever an element is processed, it goes into a set of size at least double, hence each element is processed at most $\log n$ times

Partition-Based Implementation

- ◆ A partition-based version of Kruskal's Algorithm performs cloud merges as unions and tests as finds.

Algorithm Kruskal(G):

Input: A weighted graph G .

Output: An MST T for G .

Let P be a partition of the vertices of G , where each vertex forms a separate set.

Let Q be a priority queue storing the edges of G , sorted by their weights

Let T be an initially-empty tree

while Q is not empty **do**

$(u,v) \leftarrow Q.\text{removeMinElement}()$

if $P.\text{find}(u) \neq P.\text{find}(v)$ **then**

 Add (u,v) to T

$P.\text{union}(u,v)$

return T

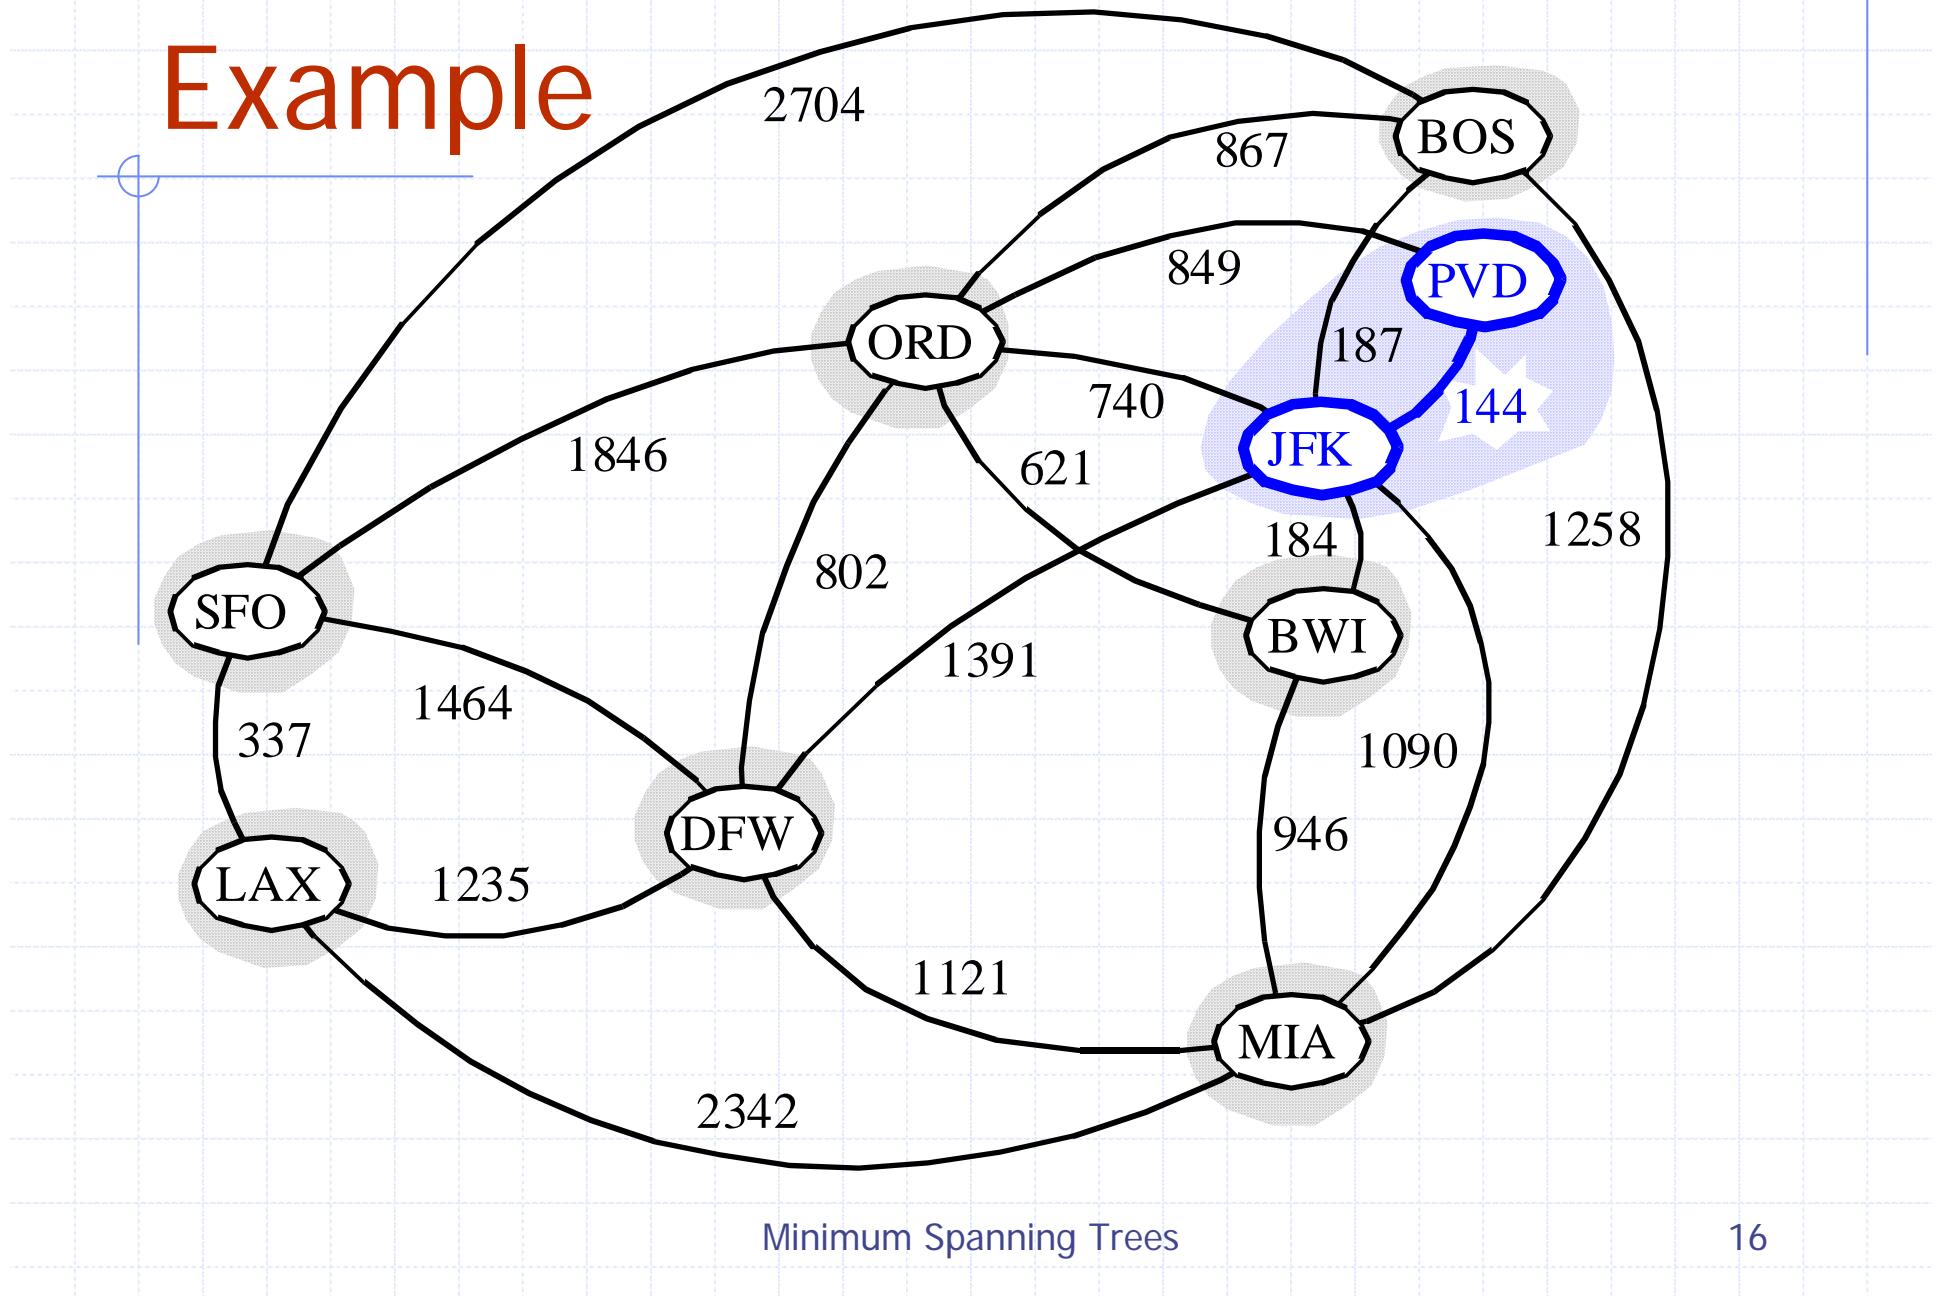

Running time:
 $O((n+m)\log n)$

Baruvka's Algorithm

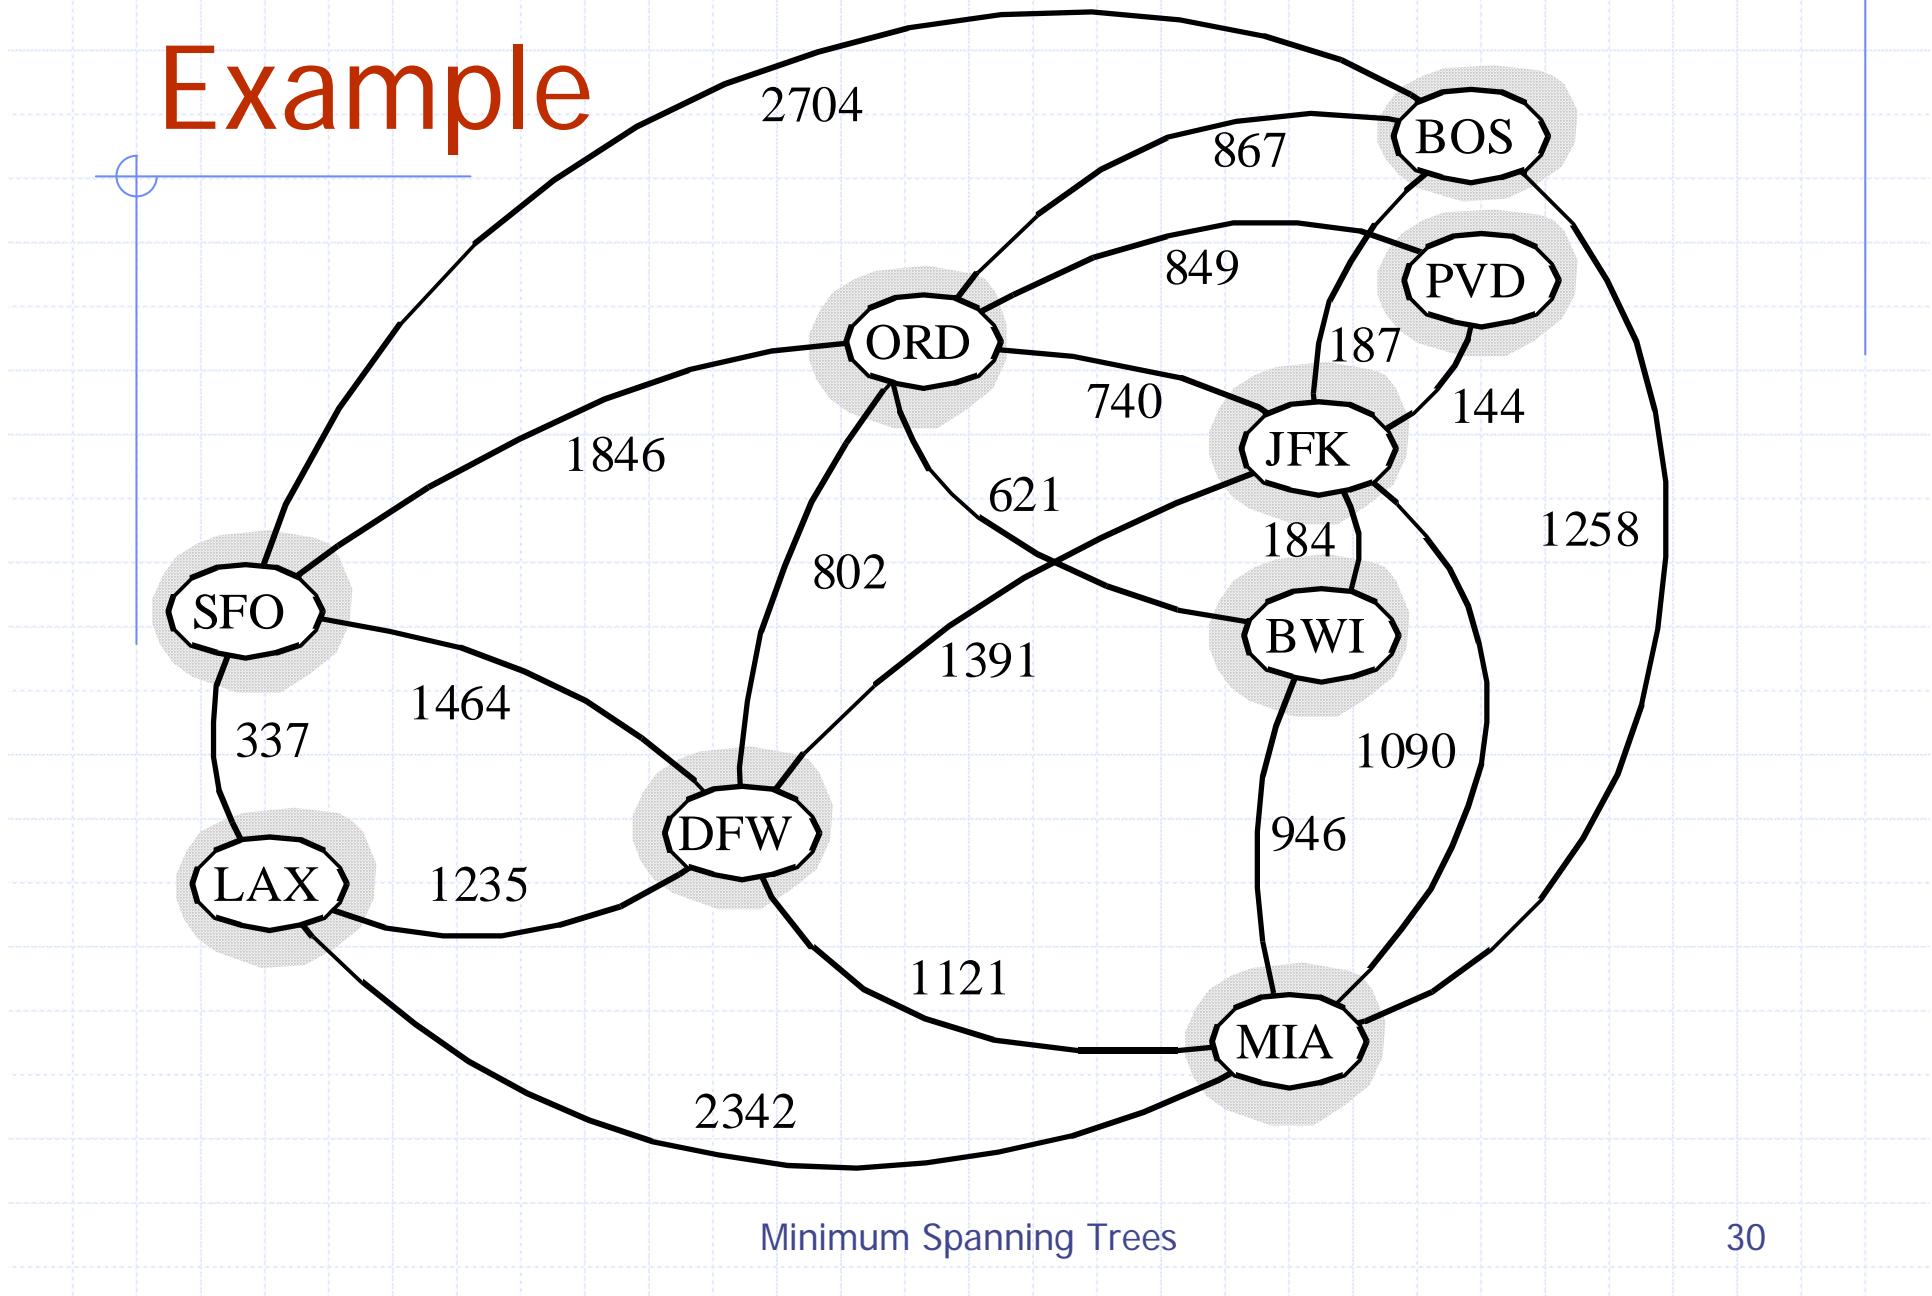

- ◆ Like Kruskal's Algorithm, Baruvka's algorithm grows many "clouds" at once.

Algorithm *BaruvkaMST(G)*

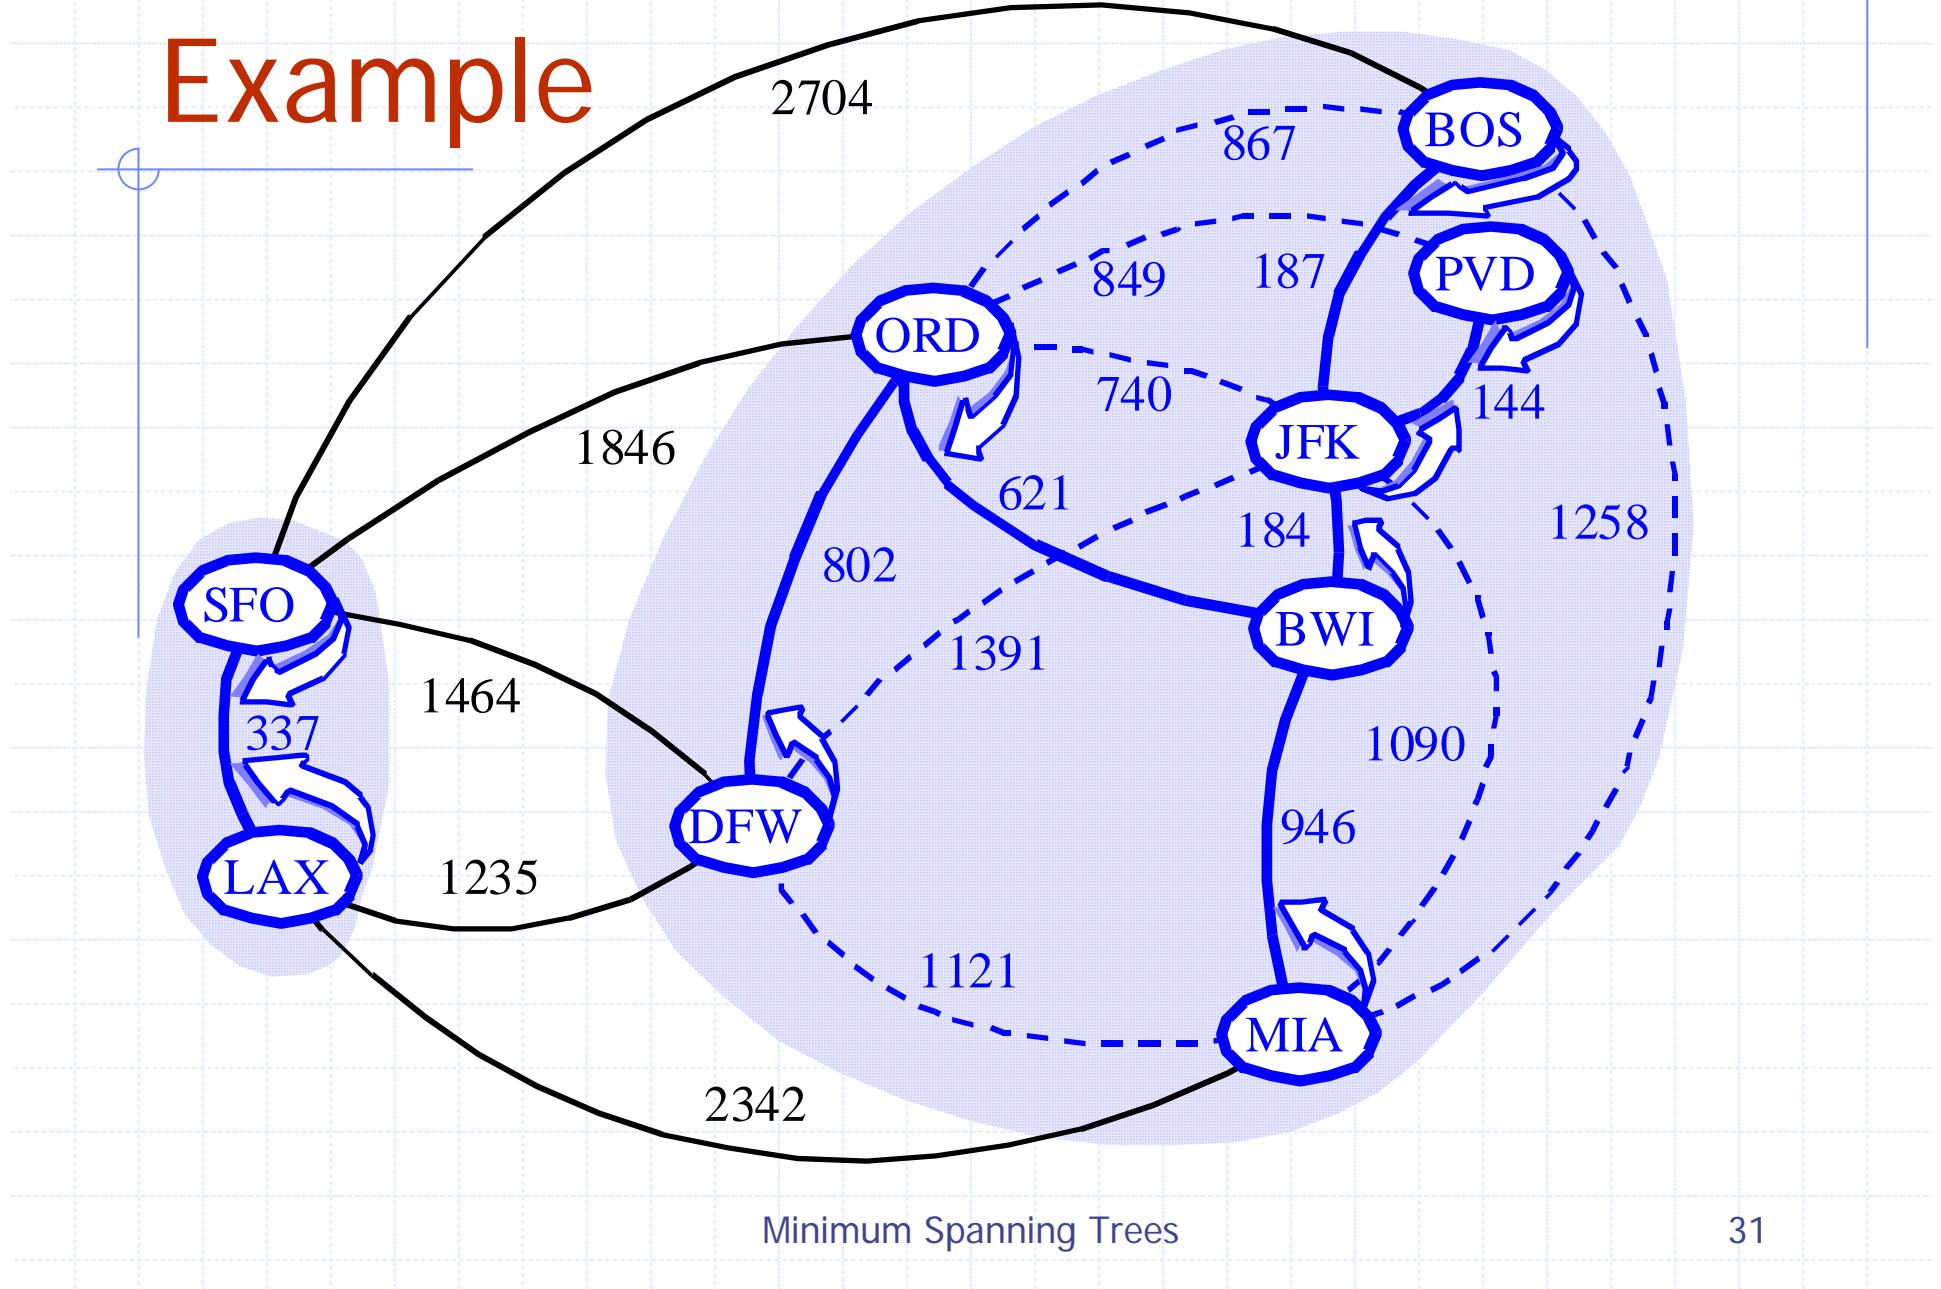

```
 $T \leftarrow V$  {just the vertices of  $G$ }  
while  $T$  has fewer than  $n-1$  edges do  
  for each connected component  $C$  in  $T$  do  
    Let edge  $e$  be the smallest-weight edge from  $C$  to another component in  $T$ .  
    if  $e$  is not already in  $T$  then  
      Add edge  $e$  to  $T$   
return  $T$ 
```

- ◆ Each iteration of the while-loop halves the number of connected components in T .
 - The running time is $O(m \log n)$.
